# Experiment - 13

Student Name: Ajay Pratap Devra
Branch: CSE - AIML
Semester: 5
Subject Name: ADBMS

UID: 24BAI70645
Section/Group: 24AIT_KRG-1_B
Date of Performance: 5/10/26
Subject Code: 24CSP-310

***Aim:*** To study Amazon RDS, create a database instance on AWS RDS, understand security groups, and connect a cloud RDS database to a local database client such as pgAdmin.

***Software used:***

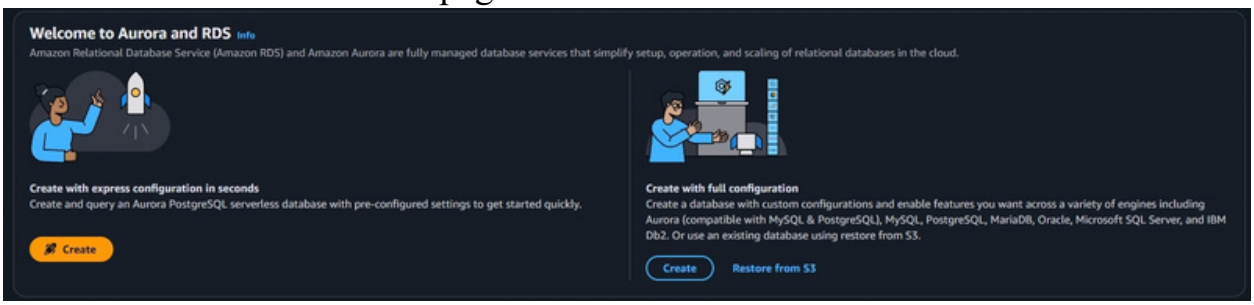

AWS Management Console / AWS account
Amazon RDS
pgAdmin (for the PostgreSQL local-connection approach)

***Theory:***

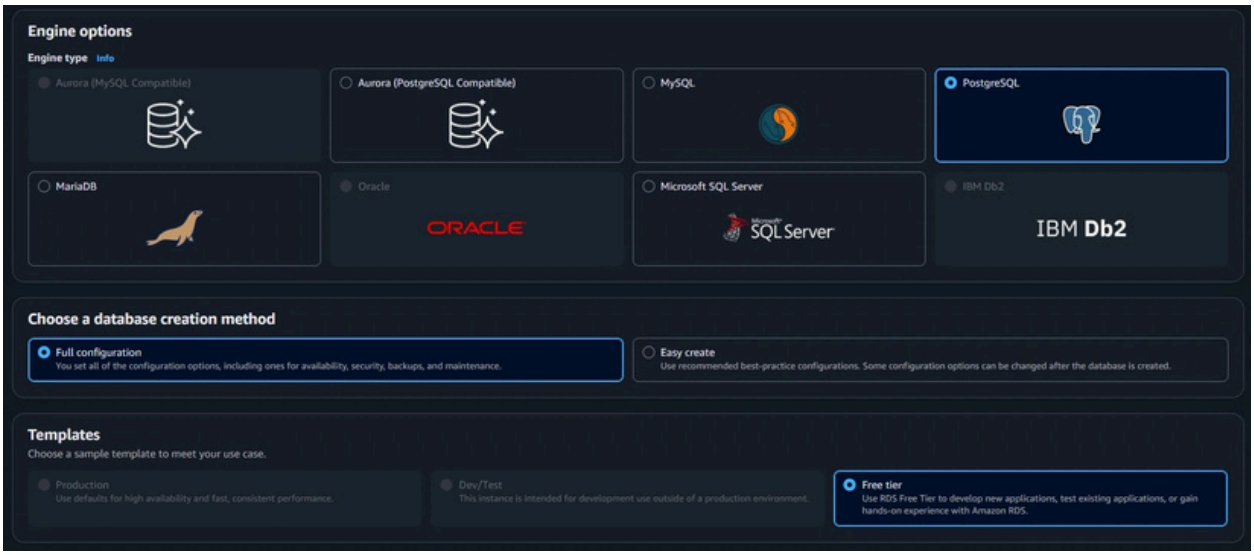

Amazon RDS is a managed relational database service provided by AWS. The guidelines focus on scalability, performance, advanced security, cost-effectiveness, manageability, availability and durability.
The experiment contrasts databases running on EC2 with RDS. Running a database on EC2 can provide OS access, advanced DB option tuning, vendor-specific requirements and versions not provided by AWS, but it also introduces administration, backup/DR, monitoring and setup overhead.

***Steps:***

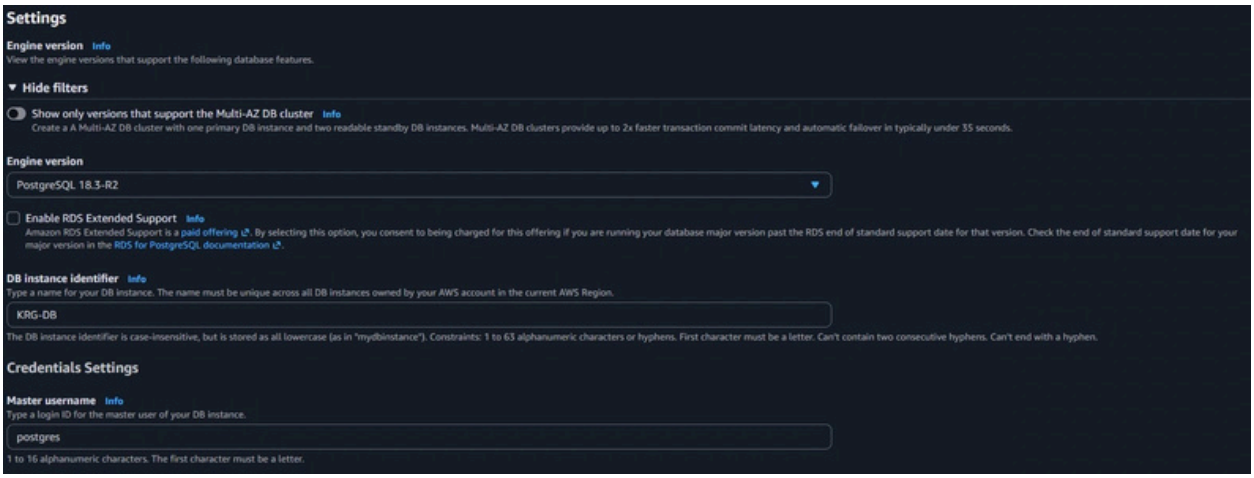

1. Go to AWS RDS homepage

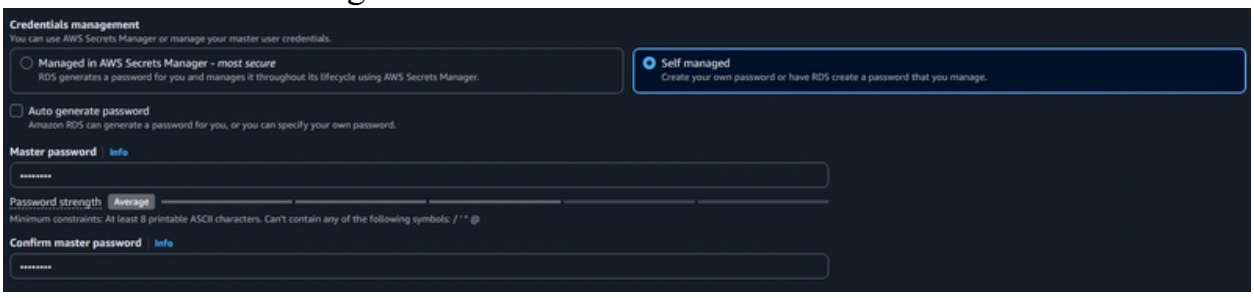

2. Select PostgreSQL provider

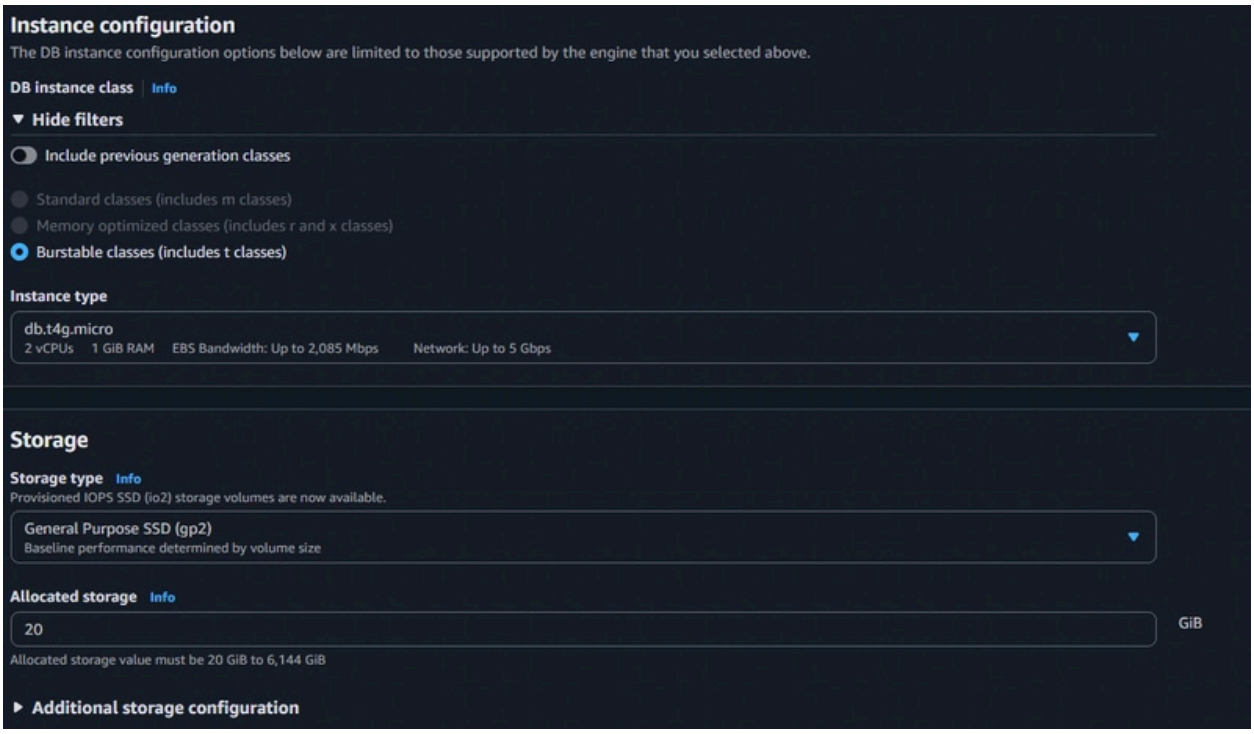

3. Set DB Instance Identifier

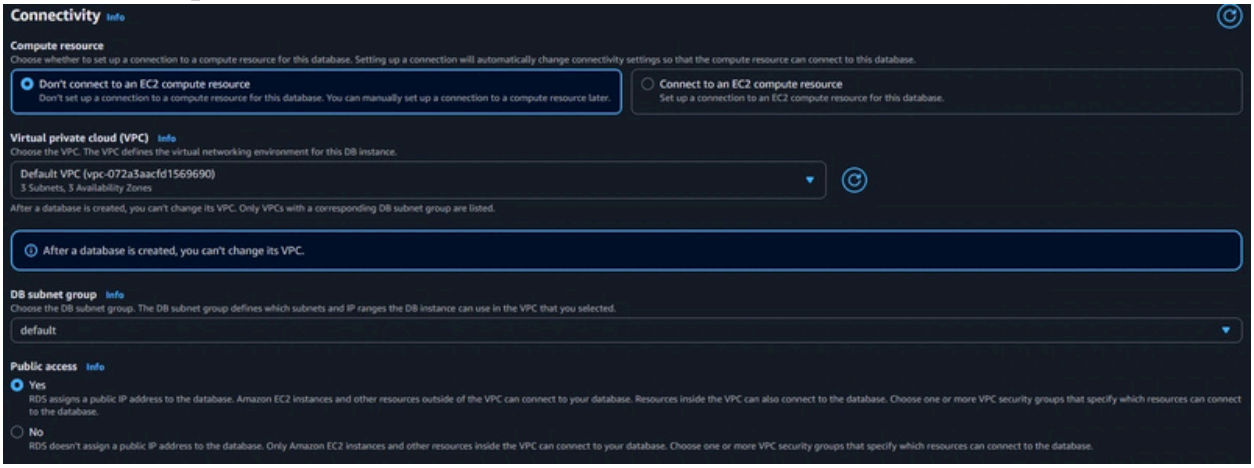

4. Select Self-Managed and set Master Password

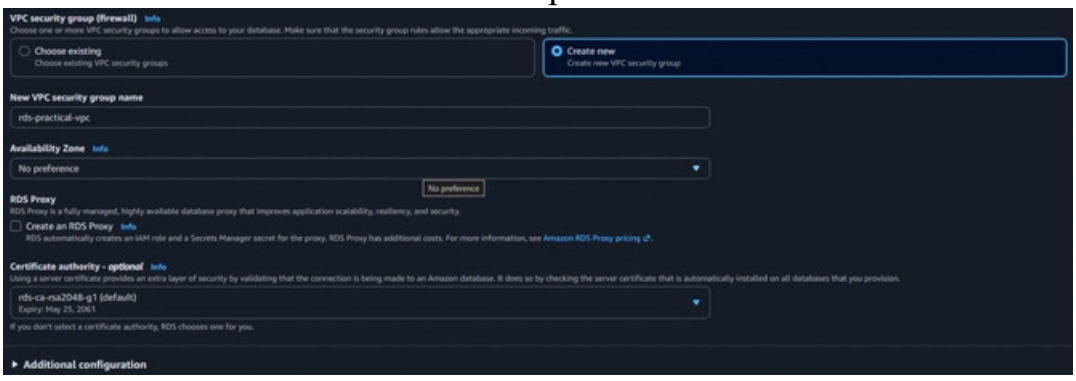

5. Select the required instance type

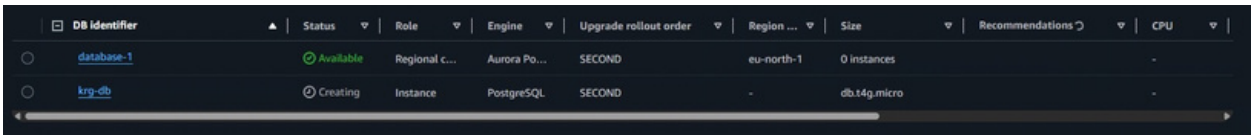

6. Allow public access

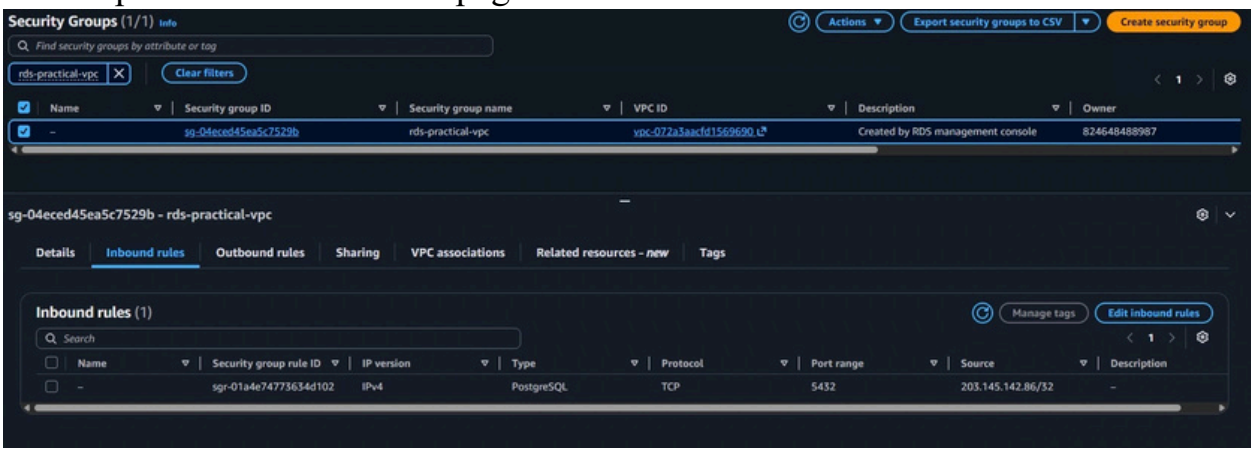

7. Create custom VPC rules if required

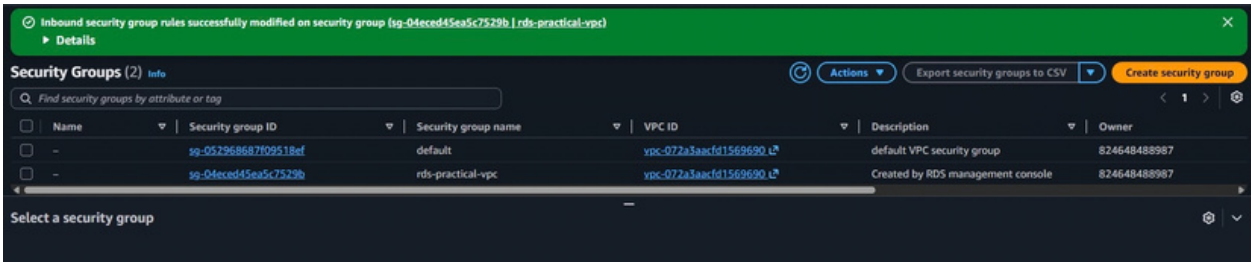

8. Wait for DB to start

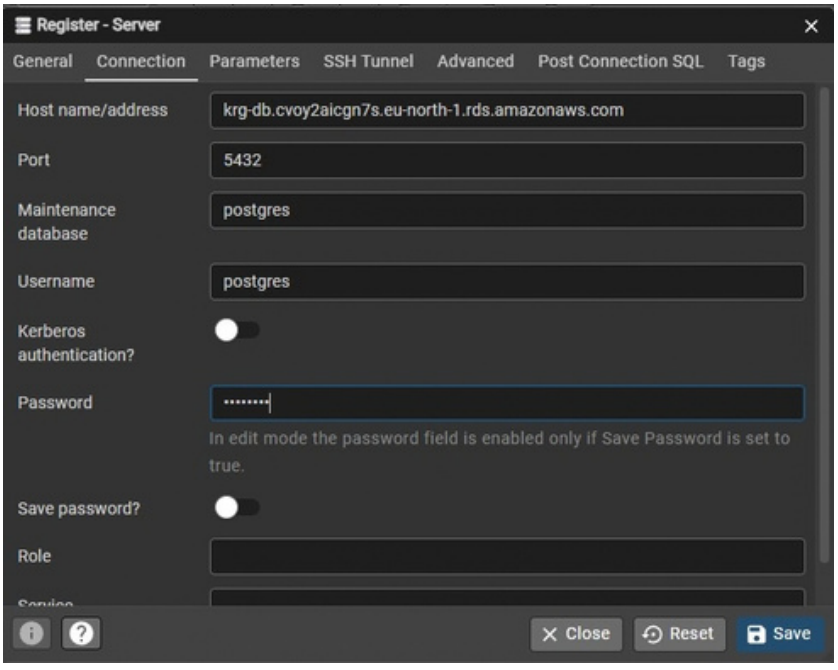

9. Open the InBound rules page

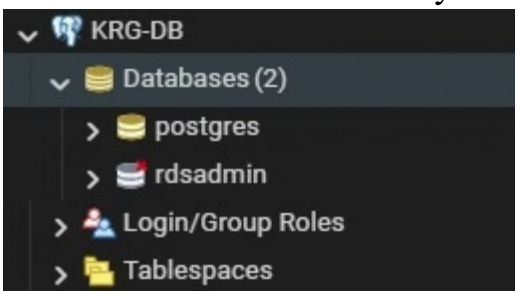

10. Add the host IP address

11. Register the server in PgAdmin

12. The DB is successfully added

13. Verify connection
